GCP acquisition using simulated SAR derived from DTM.

Kohei Arai, Nobuyoshi Fujimoto

Earth Observation Center, National Space development Agency of Japan.

#### Abstract

: A method for the GCP acquisition using simulated SAR image, derived from Digital Terrain Model, DTM, is proposed. The Japanese Earth Resource Satellite-1, JERS-1, will be launch in 1992. Before that, it will be better preparing GCPs for the precise geometric correction of SAR image data. In order to acquire GCPs without real SAR image data, SAR image has been simulated by using DTM. In this study, simulated image is derived from elevation data only so that suppose the simple scattering model without consideration of complex conductivity. Performance of the acquired GCPs has been evaluated by using some measurs for considering automatic GCP acquisition. Some effect by window size of GCP chip, include GCP in center of it, has been investigated. This paper described the detail of the proposed mothod and results of investigations, to determine whether control points can be automatically acquired in the simulation image study.

Presented at the ISPRS held in Kyoto, Japan, in July 1988.

1. Introduction

For many years, methodology for GCP acquisition of optical imaging sensor data have been proposed and studied. Such techniques are applicable for SAR images effectively according to the recent investigations (B.guindon, et, al 1983,1985,1987). Ref. 1 showed the method for automatic matching of topographically distorted real SAR image and simulated image.

Real $S A R$ images have geometric distortions caused by satellites attitude and position changes and their estimation accuracies result in skew, rotation, offset, magnification errors.

Japanese ERS-1 will be launched with the mission instruments SAR and OPS, in 1992. Before the launching of J-ERS1, GCPs for geometric accuracy assessment of SAR should be created. Therefore by using simulated images generated from DTM prepared by Geographic Survey Institute of Japan, acquisition of GCPs were attempted. In this process, some measures were tried to represent goodness of the candidate GCPs in terms of cross correlation between raw and geometrically distorted GCP chip images. This paper describes the method for simulation of SAR image at first. Second texture features will be introduced for representation of goodness of GCPs. Then some results from the experiments on matching accuracy between simulated and artificially distorted SAR image chips. Finally, comparative study of texture features in terms of cross correlation will also be described.

## 2. Simulation of SAR image.

### 2.1 Mesh data and interpolation

Numerical Geographic data of Japan including DTM and/or DEM are available on the standard magnetic tape file. The file (file code KS-110-1) has terrain height data with one meter step, according to the format called "Standard Area Mesh System" Ref. 8.

The area $(80 \mathrm{~km} * 80 \mathrm{~km}$ wide, corresponding to $1 / 200,000$ topographic map) has been extracted from intensive study area, because no data loss(KS-110-1 has no data for the sea area), and contain rugged mountain area. This area includes Mt. Fuji as shown in Fig. 1. Although the Original mesh grid distance is 250 m , data are interpolated with the interval of 50 m by 3dimensional spline function.

### 2.2 Expression of backscattering

Assuming that backscattering coefficients are almost same in the area because it almost covered by Lambertian surface of forest. Geometric relationship between the satellite and the targets is shown in Fig.3. Also assuming that satellite is located west side of the area, altitude is 570 km , side looking angle is 35 deg, satellite course is along to longitude line during observation.

Image was simulated according to the following algorithm.

1) Elevation between the neighboring grids is derived from the DTM data.
2) Calculate the incidence angle of radar beam to target, and
obtains the distribution of backscattering coefficient according to the following equation, In $=\operatorname{Ir} \cos \theta$
where In:vertically incident beam; Ir:reflected beam to the direction of $\theta$.
3) Resampling the data along with the range direction according to the following equation.
The aim of this resampling is to adjust the pixel interval deformed by topographic artifacts illustrated in Fig. 4.

$$
\begin{aligned}
& P(i)=e,\left\{\left.x-1 \frac{1}{2} x-\delta x i \right\rvert\,\right\} / x \\
& P(i): \text { Pixel value of resampled data } \\
& \text { ei : Pixel value of before resample } \\
& X i \\
& \delta X i \quad: \begin{array}{l}
\text { Standard pixel distance } \\
\\
\\
\text { artifacts of distortion by topographic related }
\end{array}
\end{aligned}
$$

4) Divide the image into $10 * 10$ chips. These chips consist of 32 lines by 32 pixels. The gray level variance of these chips are indicated in Table 1. 14 chips which were selected for the study is illustrated in Table 1-2, and also shown in Fig. 5.
3. Automatic matching of GCP chip to the artificially distorted image.

The original image was distorted by skew and rotation to represent the geometric distortion, then area correlation was calculated between the original chip image and the distorted chip. The chip what has max correlation coefficient to be decided the matching target.

1) Extracted the reference image chip ( 64 pixel by 64 line around the GCP) and distorted this chip by skew and/or rotation.
2) Set the searching window (48 pixel by 48 line).
3) Move the GCP chip, pixel by pixel, in the searching window.

Skew and rotation range 0 to 4 deg. To refine the coarsely estimated location, a 3*3 area, centered on the peak correlation is extracted and using 2-dimensional polynomial for interpolation refined peak is found. On the other hand, 0 to 10 degree distortions are considered for GCP NO.1-3 to investigate the case of which miss identification is more than one pixel. These 3 chips are also used for investigation of chip size effect. Chip size of ( $32 * 32,28 * 28,24 * 24,20 * 20,16 * 16,12 * 12$ ) are considered.
4. Texture features of the GCP chips.
4.1 Method

To assess goodness of GCP, texture features are taken into account due to the fact that gray level variance indicated in Table 1 , do not always represent busyness of the terrain surface. In this study, GLCM (Gray Level Co-occurrence Matrix) proposed by Haralick et al (1973) was used 256 levels were suppressed into 125 levels for computational convenience. GLCM was normarized
by the following equation.

$$
\begin{align*}
& P(i, j, d, \theta)=\frac{P(i, j, d, \theta)}{R}  \tag{3}\\
& R=\quad(P(i, j, d, \theta))^{R}
\end{align*}
$$

Ng : number of gray levels
P(i,j) :element of GLCM
d :pixel distance (1 or 2)
Ө : 0,45,90,135 deg.
Texture features were computed by the following equations.
i) Contrast
$\mathrm{CON}=\sum_{\mathrm{i}} \sum_{j}(\mathrm{i}-\mathrm{j})^{2} \mathrm{P}_{\mathrm{i} \downarrow}$
ii) Chi-Square

CHI $=\sum_{i} \sum_{j} \frac{P_{i j}{ }^{2}}{P_{x}(i) P_{y}(j)}$
iii) Entropy

ENT $=\Sigma \Sigma P_{i j} 10 g P_{i j}$ j
iv) Angular Second Moment

$$
\begin{equation*}
A S M=\sum_{i} \sum_{j} P_{i j}{ }^{2} \tag{7}
\end{equation*}
$$

v) Homogeneity

$$
\begin{equation*}
\text { HOM }=\sum_{i} \sum_{j} \frac{P_{i j}}{1+(i-j)^{2}} \tag{8}
\end{equation*}
$$

vi) Dissimilarity

$$
\begin{equation*}
\text { DIS }=\Sigma \Sigma|\mathrm{i}-\mathrm{j}| \mathrm{P}_{\mathrm{i}} \tag{9}
\end{equation*}
$$

vii) Correlation

$$
\begin{equation*}
\operatorname{COR}=\left\{\sum_{i} \sum_{j}(i j) P_{i j}-\mu_{x} \mu_{y}\right\} / \sigma_{x} \sigma_{y} \tag{10}
\end{equation*}
$$

Pij : element of GLCM
i,j : row and column
Px(i);Py(j) : marginal probability matrix obtained by summing the rows (columns) of $P(i, j)$
ux, uy, ox, and oy are the means and standard deviations of Px(i), Py(j)

### 4.2 Results

The computed texture features are indicated in Table 2.
Table 3 indicates miss-identification of GCPs between true GCP position and functional peak of correlation.

Variance-covariance and correlation coefficient matrices between estimation error and each texture feature are illustrated in Table 4. Fig. 6 shows that optimum size depends on the characteristic of chip.
5. Concluding Remarkes.

1) Variance do not always represents the busyness of topography while contrast and dissimilality have relatively strong negative correlation. Meanwhile entropy, angular second moment, and homogeneity have positive correlation. These values are sufficient to define the criteria for goodness of GCPs.
2) It was found that variance plays not so significient role compared to the wave number of space frequency effect.
3) It is also obvious that small size chips have been affected relatively little effect with distortions. Since the chip have little information, some hidden risks of miss-identification will be increased.
