Abstract

Conventional methods of land evaluation that use classical methods of hierarchical classification and logic analysis to determine land suitability classes have revealed some shortages and they often break down in GIS. One of the reasons is that it is depended on the mental model which couldn't be recognized by computer in GIS, another reason is the functions which influent the land classes are multiple and their variations are not in the same steps, that makes us often fall down in hesitation in determining the land level boundaries and mapping of land evaluation.

Fuzzy reasoning and the mathematical models of fuzzy multiple assessment can overcome these difficulties and be useful for land evaluation in GIS. It's basic idea is from a single membership factor assessment to the multiple membership factors assessment with fuzzy reasoning and determining the weights of every factors with the AHP model.

Introduction

Based on the ideas of FAO, land evaluation should be connected with land characteristics and land use. Together with our practice in Dalian region, Liaoning Province of China, the procedures of land evaluation in GIS are as map 1. We can obtain the land evaluation parcels map and the table of the characteristics of land evaluation parcels in GIS based on the maps of land type and land use and the tables of the characteristic of land type and land use. The next step of land evaluation is to set up the mathematical models of land evaluation for different land uses or different aims, then we can obtain the maps and the tables of land evaluation for different land uses or different aims. In this procedures, the modeling of land evaluation is very important step, sometimes it is the key one.

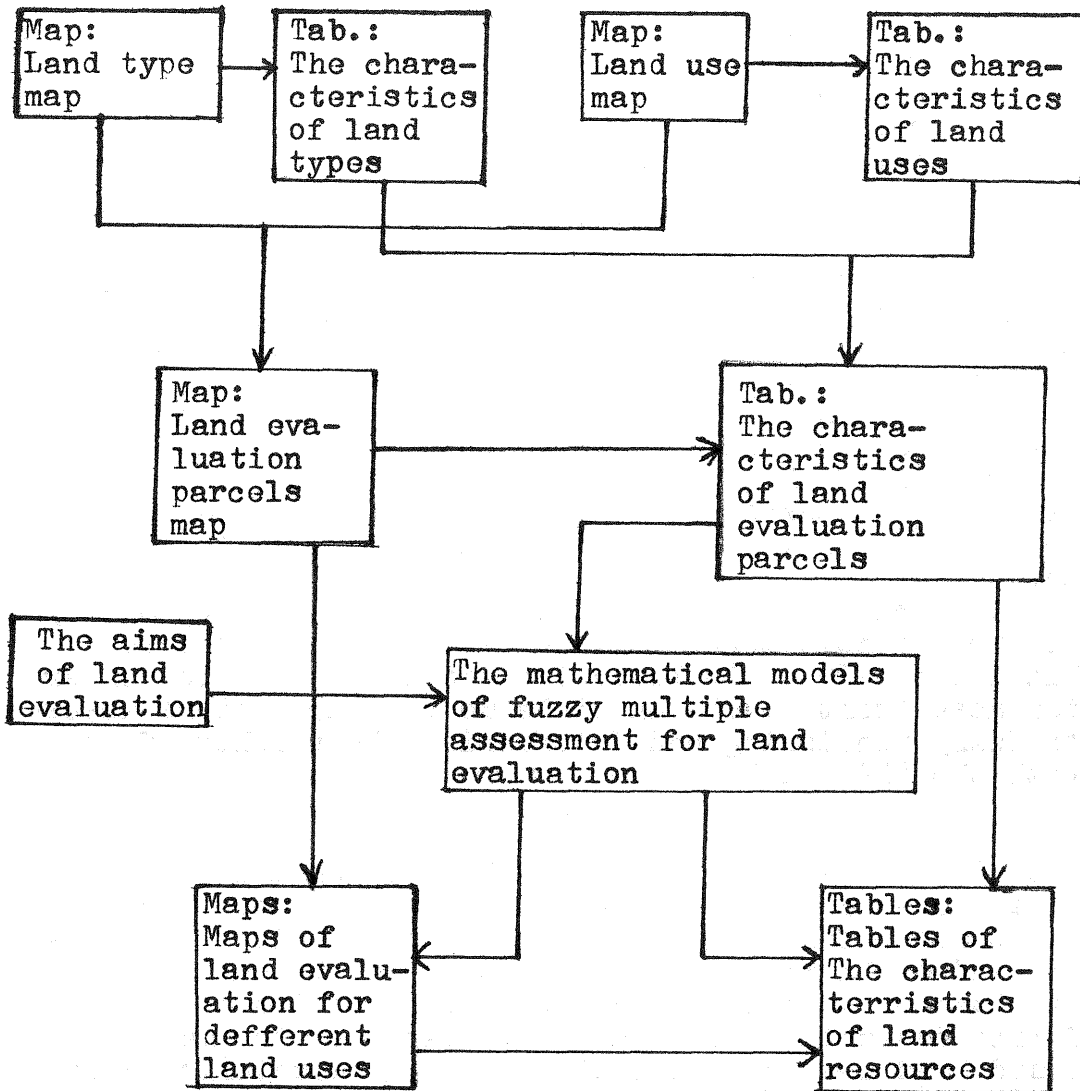

The fuzzy mathematical model of land evaluation

Fuzzy set theory as a means for dealing with inexact concepts was been produced by Zadeh in 1965. It distinguishes three kinds of inexactness:

- generality, that a single concept applies to variety of situation;
- ambiguity, that a single concept embraces more than one distinguishable sub-concept;
- vagueness, that precise boundaries are not defined.

A fuzzy set is a class that admits the possibility of partial membership. Fuzzy sets are generalisations of the usual crisp sets of situations where the class boundaries are not, or cannot be sharply defined. Currently, applications are being found in computer science and artificial intelligence and this article present one application in land evaluation.

Map 1 : The procedures of land evaluation in GIS

The fuzzy mathematical model of land evaluation is consisted of three parts:

a. A single membership function model:

$$E_i = \begin{cases} 0 & \text{for } U_i \leq C_0 \\ 1 - a_i(U_i - C_0)^2 & \text{for } C_0 < U_i < C_t \\ 1 & \text{for } C_t \leq U_i \end{cases} \quad (\text{FMM1})$$

$i=1, 2, \dots, p.$

Where C_0 defines the exact boundary condition which is not suitable land, C_t defines the land evaluation exact boundary which is suitable land completely, a_i is constant, E_i defines the land evaluation coefficient of a single membership function of

the i th land evaluation unit.

b. Multiple membership function model:

$$B_i = W_1 \cdot E_1 + W_2 \cdot E_2 + \dots + W_k \cdot E_k \quad (\text{FMM2})$$

$$= \sum_{j=1}^k W_j \cdot E_j, \quad i=1, 2, \dots, p.$$

Where B_i defines the land evaluation coefficient of multiple membership function of the i th land evaluation unit, E_j is the land evaluation coefficient of the j th membership function of the i th land evaluation unit, W_j defines the weight of the j th membership function,

where

$$\sum_{j=1}^k W_j = 1, \quad W_j > 0.$$

c. Comment model:

$$S = \begin{cases} S_1 & \text{for } V_1 < B_1 \\ S_2 & \text{for } V_2 < B_1 \leq V_1 \\ S_3 & \text{for } V_3 < B_1 \leq V_2 \\ S_4 & \text{for } V_4 < B_1 \leq V_3 \\ S_5 & \text{for } V_5 < B_1 \leq V_4 \\ S_0 & \text{for } B_1 < V_5 \end{cases} \quad (\text{FMM3})$$

where S_i defines the land suitability level, S_0 is the dissuitable land comment, V_i defines the exact boundary of every land suitability level.

When we apply the fuzzy mathematical model to evaluate land in GIS, we need finish below steps:

- we need a set of possible land evaluation units, which we can finish based on the maps of land type and land use;
- we need a set of membership functions and a set of the characteristics of every land evaluation units about the membership functions, which we can finish based on the tables of land type and land use;
- for each land characteristic we need a standard index to define full membership of the fuzzy set, and we need to set the values for the crossover points that determine the dispersion indices of the set, which we can finish based on the experts' experiences, note that all these indexes or values are different for different aims of land evaluation or different regions where the land will be evaluated;
- we need a set of weights to relate the importance of the land characteristics to each other, which we will finish by applying the AHP model (Analytical Hierachy Process).

The AHP model to determine the weights of land evaluation membership functions

The AHP model as an analytical means for the importance of every factors in a complex system which includes many factors was been produced by A.L.Saaty in 1970's. It distinguishes the factors into different levels which are related to each other.

Based on the judgement relative importance between the factors in the same level, calculate the weights of every factors, the main function of the AHP model in land evaluation is to determine the weights of every membership functions which are related with land evaluation. The basic theory of AHP as below:

$$A = \begin{pmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \vdots \\ a_{n1} & a_{n2} & \dots & a_{nn} \end{pmatrix} = (a_{ij})_{n \times n}$$

where a_{ij} defines the relative importance coefficient of the i th factor to the j th factor, that is obviously:

$$a_{ii} = 1, a_{ij} = 1/a_{ji} \quad (i, j=1, 2, \dots, n)$$

and

$$AW = \begin{pmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \vdots \\ a_{n1} & a_{n2} & \dots & a_{nn} \end{pmatrix} \cdot \begin{pmatrix} W_1 \\ W_2 \\ \vdots \\ \vdots \\ W_n \end{pmatrix} = \begin{pmatrix} nW_1 \\ nW_2 \\ \vdots \\ \vdots \\ nW_n \end{pmatrix} = nW$$

$$\sum_{i=1}^n W_i = 1$$

when $a_{ij} = a_{ik}/a_{jk} \quad (i, j, k=1, 2, \dots, n)$

then $AW = \lambda_{\max} W$ and finally we can obtain W .

When we apply the AHP model to calculate the weights of every membership functions, we need finish below steps:

--- we need to divide the issues into different levels, the highest level is the aim level of land evaluation, the lowest level is the membership functions level, and the middle levels may be sub-aim level or the sets level which are consisted of some factors. Between the levels there are some relationship line to connect them;

--- making the judgement matrix: the judgement matrix shows the relative importance of the factors in the same level and all these factors are related to one factor which is located in the higher level. Support A_k , which is located in the A level, is related to the B_1, B_2, \dots, B_n , which are in the B level, the judgement matrix is:

| A_k | B_1 | B_2 | \dots | B_n | W_i |
|----------|----------|----------|----------|----------|----------|
| B_1 | b_{11} | b_{12} | \dots | b_{1n} | W_1 |
| B_2 | b_{21} | b_{22} | \dots | b_{2n} | W_2 |
| \vdots | \vdots | \vdots | \ddots | \vdots | \vdots |
| \vdots | \vdots | \vdots | \vdots | \vdots | \vdots |
| B_n | b_{n1} | b_{n2} | \dots | b_{nn} | W_n |

Where b_{ij} is the relative importance coefficient b_i to b_j , for A_k , usually $b_{ij} = (1, 2, \dots, 9)$, or $(1, 1/2, 1/3, \dots, 1/9)$.

The more the coefficient is, the more important the factor is;

--- calculate the weights of the factors in the same level: to calculate the weights of the factors in the same level, we can use the equation:

$BW = \lambda_{\max} W$ where B defines the adjugement matrix, λ_{\max} is the maximum characteristic root, W is the characteristic vector for λ_{\max} .

In order to test the consistent of the adjugement matrix and whether it is satisfiable, we need to calculate it's consistent index CI and radom consistent radio CR:

$$CI = \frac{\lambda_{\max} - n}{n-1}, \quad CR = CI/RI,$$

where RI is average redom consistent index.

| | | | | | | | | | |
|-------|------|------|------|------|------|------|------|------|------|
| order | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
| RI | | | 0.58 | | 1.12 | | 1.32 | | 1.45 |
| RI | 0.00 | 0.00 | | 0.90 | | 1.24 | | 1.41 | |

If $CR < 0.10$, the adjugement matrix is satisfied consistent, and now we can finish the W ;

--- calculate the weights of the factors at the total level, we can obtain the $W_{b1}, W_{b2}, \dots, W_{bn}; W_{c1}, W_{c2}, \dots, W_{cn}$, then we can calculate the total weights of the factors:

$$W_{cj} = \sum_{i=1}^n b_i c_j^i \quad (i=1, 2, \dots, n, j=1, 2, \dots, m)$$

Table 2: The total weights of the factors being in the level C

| level B level C | B_1 | B_2 | | B_n | The total weights of the factors being in the level C |
|--------------------|---------|---------|-------|---------|---|
| | b_1 | b_2 | | b_n | |
| C_1 | c_1^1 | c_1^2 | | c_1^n | $W_{c1} = \sum_{i=1}^n b_i c_1^i$ |
| C_2 | c_2^1 | c_2^2 | | c_2^n | $W_{c2} = \sum_{i=1}^n b_i c_2^i$ |
| ⋮ | ⋮ | ⋮ | | ⋮ | ⋮ |
| C_m | c_m^1 | c_m^2 | | c_m^n | $W_{cm} = \sum_{i=1}^n b_i c_m^i$ |

$$\sum_{j=1}^m \sum_{i=1}^n b_i c_j^i = 1 ;$$

--- test the consistent of the total weights. The model of testing the consistent of total weights is similar to the step two:

$$CI_t = \frac{\sum_{i=1}^n b_i CI_i}{\sum_{i=1}^n b_i RI_i} \quad RI_t = \sum_{i=1}^n b_i RI_i \quad CR_t = CI_t / RI_t$$

if $CR_t < 0.10$, then the adjugement matrix is satisfied consistent.

An example to use the fuzzy mathematical model of land evaluation

In order to explain how to use the fuzzy mathematical model of land evaluation, a simplified example about land evaluation in the suburban district of Dalian City of China is produced. The Dalian City is a large city in China, there are more than 1.5 million population in it. The main aim of the land use of the suburban district is to serve for the city. In order to use land economically, land evaluation become very important. Here gives the land evaluation for agriculture land.

--- Twenty two land evaluation units were identified based on the maps of land types and land uses in GIS (Table 2);

--- The relevant land characteristics are:

- U₁: the depth of soil (cm)
- U₂: the slope gradient (per cent)
- U₃: soil texture grade
- U₄: soil organic matter content (per cent)
- U₅: PH
- U₆: irrigation condition
- U₇: the size of the parcels (per cent)
- U₈: soil erosion
- U₉: flood hazard
- U₁₀: management level
- U₁₁: production value (yuan)

--- The membership function for each land characteristic is of the form given in page 2 (a single membership function model) the same form of the membership function is used for all land characteristics.

The standard indices C_i for each land characteristic are:

$$\begin{array}{llll} C_1 = 90 & C_2 = 5 & C_3 = 1 & C_4 = 30 \\ C_5 = 6.5 & C_6 = 80 & C_7 = 2 & C_8 = 1 \\ C_9 = 1 & C_{10} = 4 & C_{11} = 800 & \end{array}$$

The values for the crossover point indices a_i are:

$$\begin{array}{llll} a_1 = 0.0002 & a_2 = 0.0055 & a_3 = 0.1013 & a_4 = 0.31 \\ a_5 = 0.62 & a_6 = 0.0004 & a_7 = 0.0047 & a_8 = 0.065 \\ a_9 = 0.25 & a_{10} = 0.132 & a_{11} = 0.0000007 & \end{array}$$

--- Use the AHP model to calculate the weights of every factors
a. divide the issues of agriculture land evaluation into three levels:

c. Calculate the total weights of the factors being in the level C:

Based on the equation $W_{ij} = \sum_{i=1}^n b_i c_j^1$ (j=1,2,...,m)

we can calculate the total weights of the factors in the level C, the results are:

| factor Ci | C1 | C2 | C3 | C4 | C5 | C6 | C7 | C8 | C9 | C10 | C11 |
|------------------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| the total weight of Ci | 0.090 | 0.166 | 0.056 | 0.019 | 0.017 | 0.156 | 0.075 | 0.054 | 0.104 | 0.126 | 0.137 |

--- Based on the fuzzy mathematical model of land evaluation including equation FMM1, FMM2 and FMM3, the results of land evaluation can be finished. (V1=0.95, V2=0.90, V3=0.80, V4=0.76, V5=0.66)

Table 4. The results of land evaluation including the results of a single factor, multiple factors and the comments.

| land evaluation units | C1 | C2 | C3 | C4 | C5 | C6 | C7 | C8 | C9 | C10 | C11 | M | S |
